Some like it hot – Biomolecule Analytics using Microscale Thermophoresis (MST)

Dr. Piotr Wardęga,

NanoTemper Technologies GmbH, Munich, Germany

The presentation gives an overview of Microscale Thermophoresis (MST), a new technology for the measurement of biomolecule interactions. The term Microscale Thermophoresis refers to the directed movement of molecules in optically generated microscopic temperature gradients. This thermophoretic movement is determined by the entropy of the hydration shell around the molecules. Almost all interactions between molecules and virtually any biochemical process are linked to a change in size, charge and/or conformation of molecules which alter this hydration shell and therefore can be detected and quantified by MST.

Microscale Thermophoresis allows quantification of binding affinities of proteins, nucleic acids and small molecules as well as measurement of enzymatic activities. In addition also functional studies of small molecule inhibitors are possible. The steep microscopic temperature gradient is generated by an IR-Laser, which is strongly absorbed by water. The readout method of the interaction analysis is based on fluorescence: fluorescently labeled proteins/peptides/nucleic acids can be used as well as intrinsic tryptophan fluorescence or proteins expressed with GFP/YFP/RFP.

The presentation will cover: 1) Technical details and benefits of the Microscale Thermophoresis technology platform and 2) Examples of interaction measurements ranging from protein – ribosome, protein – protein, small molecule – receptor down to protein – ion binding studies to experiments where the interactions between receptors incorporated in vesicles and soluble proteins are analyzed.

Date: 21.01.2014
Time: 10:00
Location: Room B-204, Jagiellońska Street 28
University of Silesia

After the seminar we offer a possibility to measure various samples on the Monolith NT.115 instrument

If you are interested in testing your own samples or have any question, please send email to:
